# An introductory course on General Purpose Computing on GPUs

#### Part II

#### Francesco Lettich

Insight Lab Universidade Federal do Ceará, Fortaleza, Brasil

#### Introduction

\* Today we are going to introduce an extensively used operation in GPU-based applications.

This operation is called **scan**.

- \* Exercise: I will ask you to implement a few versions of this operation on GPU.
- The goal is to make you aware of some of the challenges behind coding GPU algorithms.

#### Scan

#### Definition:

The all-prefix-sums operation takes a binary associative operator  $\oplus$  with identity I, and an array of n elements

$$[a_0, a_1, ..., a_{\underline{n}-1}]$$

and returns the ordered set

$$[I, a_0, (a_0 \oplus a_1), ..., (a_0 \oplus a_1 \oplus ... \oplus a_{n-2})].$$

Example:

if  $\oplus$  is addition, then scan on the set

[3 1 7 0 4 1 6 3]

returns the set

[0 3 4 11 11 15 16 22]

Exclusive scan: last input element is not included in the result

## Scan / 2

- Scan is a simple and useful parallel building block
  - Convert recurrences <u>from sequential</u> ...

```
for (j=1; j< n; j++)
out [j] = out[j-1] + f(j);
```

... into parallel:

```
forall(j) in parallel
    temp[j] = f(j);
scan(out, temp);
```

- Useful in implementation of several parallel algorithms:
  - radix sort
  - quicksort
  - String comparison
  - Lexical analysis
  - Stream compaction

- Polynomial evaluation
- Solving recurrences
- Tree operations
- Histograms
- Etc.

Implementing the sequential version of this operation is trivial on CPU:

```
void scan(float* scanned, float* input, int length)
{
  scanned[0] = 0;
  for(int i = 1; i < length; ++i)
    scanned[i] = scanned[i-1] + input[i-1];
}</pre>
```

• Complexity is O(n-1) => O(n).

#### Hillis and Steele algorithm

- \* Assume that the number of elements is a power of 2:  $n=2^{M}$ .
- → Then, at the d-th iteration the last "2<sup>M</sup>-2<sup>d</sup>" elements have to find their mate, at a distance equal to 2<sup>d</sup>, and make the sum.

\* How many iterations do we have to perform?

\* How many operations do we perform at each iteration?

What is the <u>overall amount</u> of operations?

→ How many iterations do we have to perform?

$$\log_2(n) = M$$
 (3 in the example).

\* How <u>many operations</u> do we have to perform during each iteration?

$$2^{M} - 2^{d}$$

What is the <u>overall amount</u> of operations?

Let's make some calculations...

$$M * 2^{M} - (2^{0} + 2^{1} + 2^{2} + ... + 2^{M-1}) =$$

$$M * 2^{M} - (2^{M} - 1) =$$

$$\log_{2}(n) * n - \log_{2}(n) + 1$$

- ▶ Hence, the complexity is in  $O(n * log_2(n))$ . Expensive when
- "n" gets large (example: 1 million of elements); not good if 9 compared to the work needed by the sequential solution O(n)!!!

```
__global__ void scan(float *g_odata, float *g_idata, int n)
    extern shared float temp[]; // allocated on invocation
   int thid = threadIdx.x;
   int pout = 0, pin = 1;
   // load input into shared memory.
   // Exclusive scan: shift right by one and set first element to 0
    temp[thid] = (thid > 0) ? q_idata[thid-1] : 0;
   __syncthreads();
   for( int offset = 1; offset < n; offset <<= 1 )</pre>
       pout = 1 - pout; // swap double buffer indices
       pin = 1 - pout;
       if (thid >= offset)
           temp[pout*n+thid] += temp[pin*n+thid - offset];
          else
           temp[pout*n+thid] = temp[pin*n+thid];
       __syncthreads();
    q_odata[thid] = temp[pout*n+thid1]; // write output
```

```
__global__ void scan(float *g_odata, float *g_idata, int n)
    extern __shared__ float temp[]; // allocated on invocation
   int thid = threadIdx.x;
   int pout = 0, pin = 1;
   // load input into shared memory.
   // Exclusive scan: shift right by one and set first element to 0
    temp[thid] = (thid > 0) ? q_idata[thid-1] : 0;
   __syncthreads();
   for( int offset = 1; offset < n; offset <<= 1 )</pre>
       pout = 1 - pout; // swap double buffer indices
       pin = 1 - pout;
       if (thid >= offset)
           temp[pout*n+thid] += temp[pin*n+thid - offset];
          else
            temp[pout*n+thid] = temp[pin*n+thid];
       __syncthreads();
    q_odata[thid] = temp[pout*n+thid1]; // write output
```

- \* We use the concept of **balanced trees** to implement a cleverer scan algorithm.

- \* First, "sweep" from the leaves to the root of the tree: *up-sweep*.
- \* The idea is to accumulate and propagate towards the root the partial sums of increasingly bigger partitions in the vector.

```
for d := 0 to \log_2(n) - 1 do
    for k from 0 to n-1 step 2^{d+1} in parallel do
           x[k + 2^{d+1} - 1] = x[k + 2^{d} - 1] + x[k + 2^{d+1} - 1]
                                                                                                 \Sigma(\mathbf{x}_0..\mathbf{x}_7)
                          \Sigma(x_0..x_1)
                                                  \Sigma(\mathbf{x}_0..\mathbf{x}_3)
                                                                         \Sigma(x_4..x_5)
                                         \mathbf{x}_2
                                                                 X_A
                                                                                         X_6
                  X_0
                                                                                                 \Sigma(x_4...x_7)
                                                  \Sigma(x_0..x_3)
                                                                         \Sigma(x_4...x_5)
                          \Sigma(x_c..x_1)
                                                                 X_4
                                                                                         X_6
      d=2
                  \mathbf{x}_0
                                         \mathbf{x}_2
                                                                                                 \Sigma(x_6..x_7)
                          \Sigma(x_0...x_1)
                                                  \Sigma(x_2..x_3)
                                                                          \Sigma(x_4..x_5)
                                          \mathbf{x}_2
                                                                 X_{.4}
                                                                                         X_6
      d=1
                  X_{\Omega}
      d=0
                  \mathbf{x}_0
                              \mathbf{x}_1
                                          X_2
                                                      X_3
                                                                 X_4
                                                                             X_5
                                                                                         X_6
                                                                                                     X_7
                                                                                                                          14
```

\* How <u>many iterations</u> do we have to perform during the up-sweep?

\* How many operations do we perform at each iteration?

\* What is the **overall amount** of operations during the upsweep?

\* How <u>many iterations</u> do we have to perform during the upsweep?

 $\log_2(n) = M$  (3 in the example).

→ How many sums do we have to perform during each iteration?

**2**M-d-1

◆ What is the <u>overall amount</u> of operations during the up-sweep phase?

Let's make some calculations...

$$(2^{M-1} + ... + 2^0) = 2^M - 1 = n - 1$$
 adds

- \* Hence, the complexity is in O(n 1). <u>Good!</u>
- Now we need to propagate some of the partial sums back in the right places...

Down-sweep phase: we go from the root to the leaves!

```
x[n - 1] := 0 // Init
for d := \log_2(n) - 1 down to 0 do
       for k from 0 to n-1 step 2^{d+1} in parallel do
               t := x[k + 2^d - 1]
               x[k + 2^{d} - 1] := x [k + 2^{d+1} - 1] // Copy
               x[k + 2^{d+1} - 1] := t + x [k + 2^{d+1} - 1] // Add
                                                                                                                          \Sigma(\mathbf{x}_4..\mathbf{x}_5) \mathbf{x}_6
                                                            |\Sigma(\mathbf{x}_0..\mathbf{x}_1)| \quad \mathbf{X}_2 \quad |\Sigma(\mathbf{x}_0..\mathbf{x}_3)| \quad \mathbf{X}_4
                                                                                                                                                          \Sigma(\mathbf{x}_0..\mathbf{x}_7)
                                                  \mathbf{x}_0
                                    d=0
                                                             \Sigma(\mathbf{x}_0..\mathbf{x}_1)
                                                                                           \Sigma(\mathbf{x}_0..\mathbf{x}_3)
                                                                                                                          \Sigma(\mathbf{x}_4..\mathbf{x}_5)
                                                                                 \mathbf{X}_2
                                                                                                               \mathbf{X}_{4}
                                                  \mathbf{X}_{0}
                                                                                                                                               X_6
                                    d=1
                                                             \Sigma(\mathbf{x}_0..\mathbf{x}_1)
                                                                                                                           \Sigma(\mathbf{x}_4..\mathbf{x}_5)
                                                                                                                                                          \Sigma(\mathbf{x}_0..\mathbf{x}_3)
                                                                                                  0
                                                  \mathbf{X}_{0}
                                                                                                                                               X_6
                                                                                 \mathbf{X}_2
                                                                                                                X_4
                                    d=2
                                                                                                                                                           \Sigma(\mathbf{x}_0..\mathbf{x}_5)
                                                                   0
                                                                                            \Sigma(\mathbf{x}_0..\mathbf{x}_1)
                                                                                                                          \Sigma(\mathbf{x}_0..\mathbf{x}_3)
                                                                                                                X_4
                                                                                                                                               X_6
                                                  \mathbf{x}_0
                                                                                 \mathbf{X}_2
                                    d=3
                                                    0
                                                                             \Sigma(\mathbf{x}_0..\mathbf{x}_1) | \Sigma(\mathbf{x}_0..\mathbf{x}_2) | \Sigma(\mathbf{x}_0..\mathbf{x}_3) | \Sigma(\mathbf{x}_0..\mathbf{x}_4) | \Sigma(\mathbf{x}_0..\mathbf{x}_5) | \Sigma(\mathbf{x}_0..\mathbf{x}_6)
                                                                  \mathbf{X}_{\mathbf{0}}
```

\* How <u>many iterations</u> do we have to perform during the down-sweep?

\* How many operations do we perform at each iteration?

♣ What is the <u>overall amount</u> of operations during the down-sweep?

\* How <u>many iterations</u> do we have to perform during the down-sweep?

 $\log_2(n) = M$  (3 in the example).

\* How <u>many operations</u> do we have to perform during each iteration?

$$2^{M-d-1}$$
 moves +  $2^{M-d-1}$  adds

\* What is the <u>overall amount</u> of moves and adds during the upsweep phase?

Let's make some calculations...

$$(2^{M-1} + ... + 2^{0}) = 2^{M} - 1 = n - 1 \text{ moves} +$$
the same for adds

- Hence, the complexity is in O(2(n 1)).
- \* Overall, the complexity of the Blelloch's algorithm is is O(3(n-1)) => O(n). Good!

```
global void prescan(float *q odata, float *q idata, int n)
   extern shared float temp[]:// allocated on invocation
   int thid = threadIdx.x;
   int offset = 1;
   temp[2*thid] = g idata[2*thid]; // load input into shared memory
   temp{2*thid+1} = q_idata{2*thid+1};
    for (int d = n>>1; d > 0; d >>= 1) // build sum in place up the tree
       syncthreads();
       if (thid < d)
           int ai = offset*(2*thid+1)-1;
           int bi = offset*(2*thid+2)-1;
           temp[bi] += temp[ai];
       offset *= 2;
   if (thid == 0) { temp[n - 1] = 0; } // clear the last element
   for (int d = 1; d < n; d *= 2) // traverse down tree & build scan
       offset >>= 1;
       __syncthreads();
       if (thid < d)</pre>
           int ai = offset*(2*thid+1)-1;
           int bi = offset*(2*thid+2)-1;
           float t = temp[ai];
           temp[ai] = temp[bi];
           temp[bi] += t;
   __syncthreads();
  q odata[2*thid] = temp[2*thid]; // write results to device memory
   g odata[2*thid+1] = temp[2*thid+1];
```

#### Using multiple thread-blocks

\* What if we want to extend the scan to vectors of arbitrary size?

### Exercises / 1

- **▼** To complete the exercises you will need:
  - \*Recommended O/S: Linux (e.g., Ubuntu >= 16.04).
  - \* CUDA 8.5 or 9.
  - \*A GCC version compatible with CUDA (GCC 6.x is fine).
  - \* A NVIDIA videocard.
  - Cmake.
  - (optional) Thrust library.
- \* I will also give you a little zip containing the **source code** of a little application that you will have to **complete** by providing the **required solutions**.

#### Exercises / 2

- \* Exercise 1: implement the GPU-based version of the Hill-Steele algorithm, limitedly to the case of a single thread-block.
- **Exercise 2**: implement the Blelloch's (down/up-sweep) algorithm, limitedly to the case of a **single thread-block**.
- \* Exercise 3: Adapt the code written for exercise 2 to implement the inclusive prefix sum (easy!).
- \* Exercise 4: Extend the code of exercise 2 to make use of multiple thread-blocks.
